Thank you for purchasing this asset pack! I tried to make everything self-explanatory, but this manual will help you quickly find your way around.

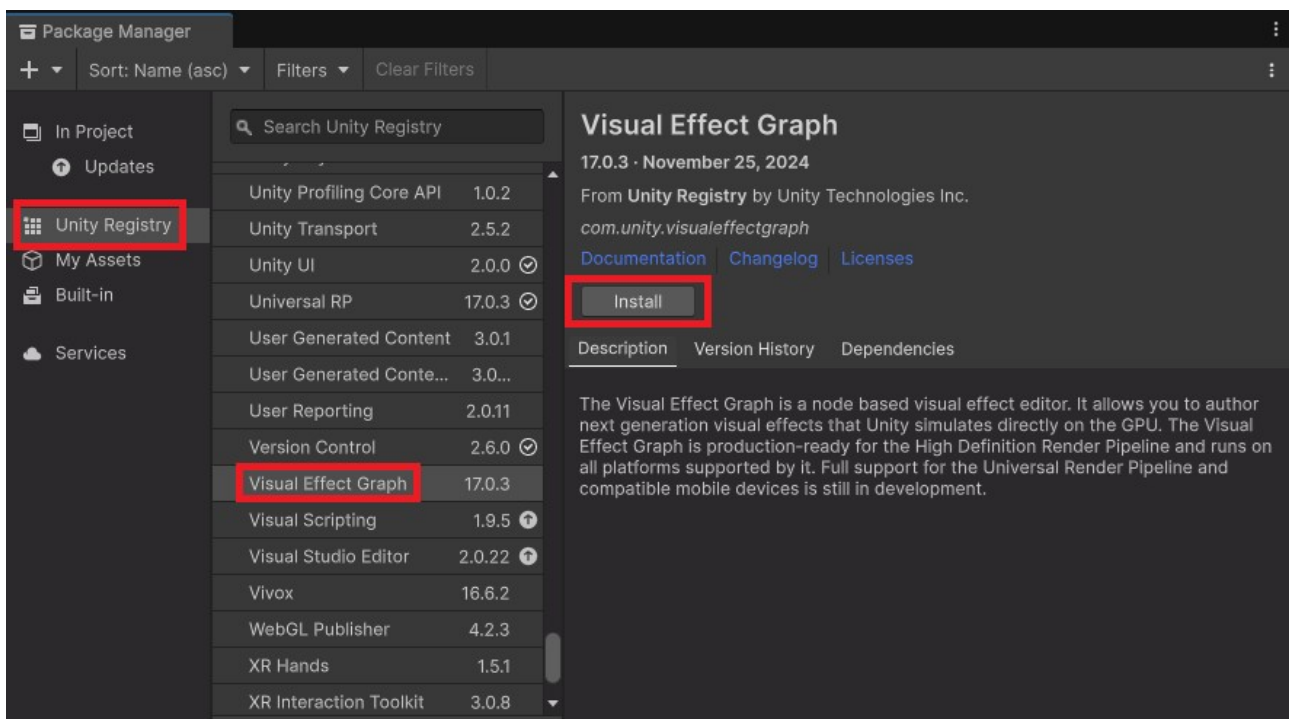

This manual contains information that is shared among all 6D VFX packs. **Details that are unique to the selected UNI VFX 6D pack can be found in the same directory as this manual.**

- [List of all available packs can be found in the Asset Store.](#)

1. Setup

Make sure you have **Visual Effect Graph** and **Shader Graph** packages installed. Go to Window → Package Manager. Find Visual Effect Graph and Shader Graph in Unity Registry Packages and install/update them if needed.

Restart the editor before installing the VFX pack.

If you install Visual Effect Graph and Shader Graph packages after this Pack, you can run into issues.

The easiest fix is to delete UNI VFX 6D folder, restart Unity Editor and install this Pack again.

For the VFX pack to work correctly in HDRP, import the HDRP package in the UNI VFX 6D folder.

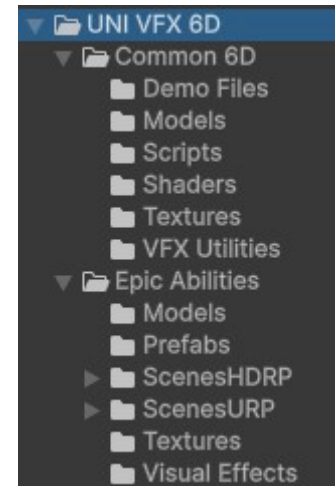

If the VFX doesn't show up, it needs to be recompiled. This can be easily fixed by using 'Edit → VFX → Rebuild And Save All VFX Graphs' in the Editor's top menu.

2. Folder structure

Main content folder is named according to the pack, for example 'Epic Abilities'. Subfolder Scenes contains:

- **Demo scene** – Easily browse VFX in Play mode.
- **Prefabs scene** – Contains all Prefabs with Loop Events turned on. Not all effects have Loop Events or they require movement to look as intended. These will only play once when they load.

'Common 6D' folder contains files that are shared among all UNI VFX 6D asset packs.

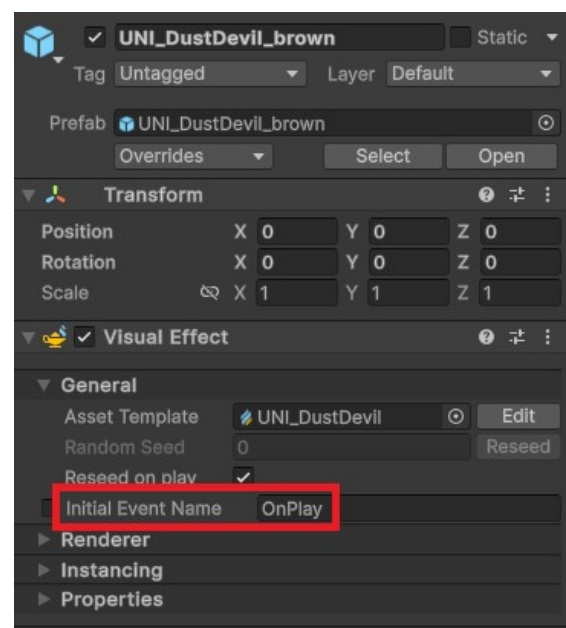

3. How to use

VFX will play Initial Event Name when spawned which is set in the Inspector. If you don't want to play any Event, leave the field blank. List of all events in each VFX pack can be found in a separate file in the same folder as this manual.

To control the VFX, you can use C# Component API [events](#).

Alternatively OnPlay and OnStop events can be triggered by effect.Play() and effect.Stop(): see [Unity manual](#).

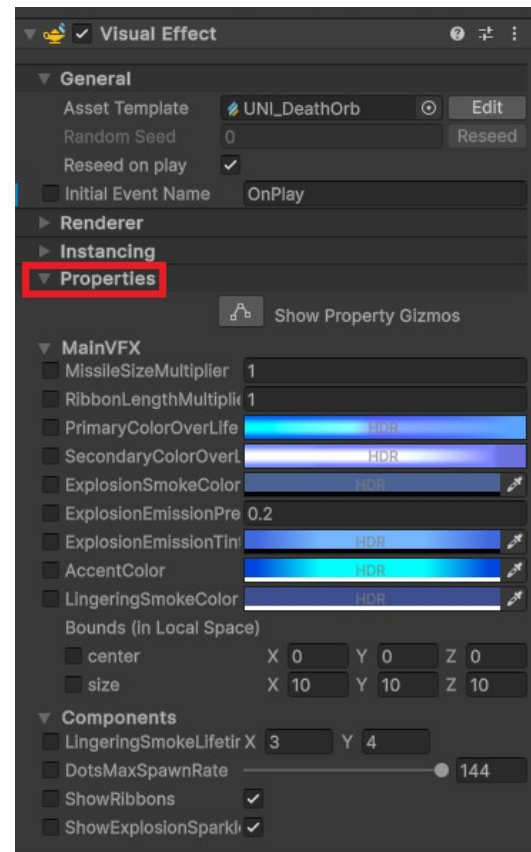

4. Tips and tricks

Tweaking

The most important effect properties are **exposed in the Inspector** so you can easily tweak effect's appearance and make your own Prefabs.

If you need even more control, you can change anything in the Visual Effect Graph. I tried to make the graphs tidy so that they would be more accessible.

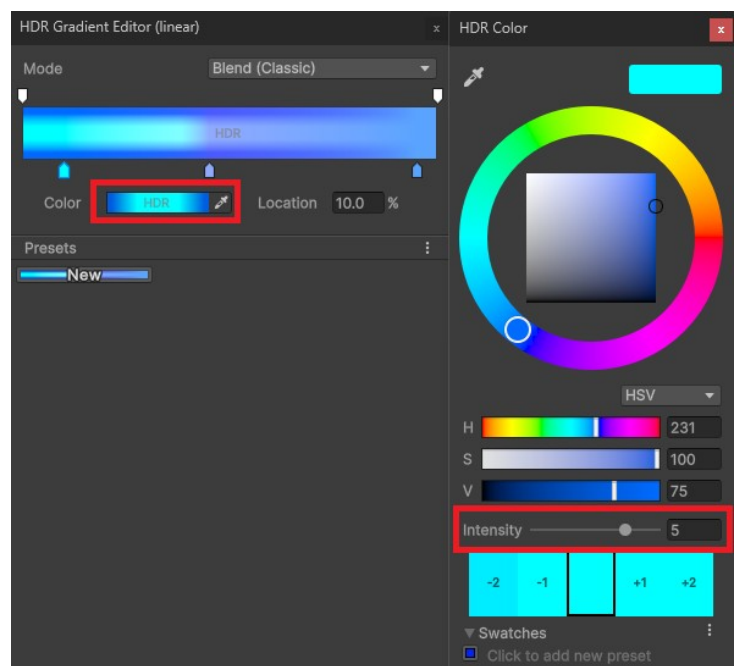

You can find [more about the Visual Effect Graph in its manual](#) or watch the [introductory video tutorial](#). If you want to go deeper, check out the [learning templates video tutorial](#).

Post-processing

Bloom and other [post-processing effects](#) can have significant impact on VFX appearance. For example the Demo scene uses Tonemapping, Bloom, Color Adjustments and Screen Space Lens Flare.

Depending on your scene and post-processing settings, you might also want to adjust the **intensity of HDR colors**. When combined with Bloom, higher values cause the effect to glow. It can be set after clicking on the gradient/color in the Inspector.

Collisions

Some VFX can use Depth Buffer collisions for selected particles. By default, this works on the camera with MainCamera tag. This means that collisions are not visible in the Scene view. Selected VFX may use a simple collision with a plane as a fallback.

Optimization

Visual Effect Graph is very powerful, but as always you should be aware of the limitations of the target hardware. Another important factor is how many effect instances can be visible at one time. You can turn off selected components and set selected particles spawn rate accordingly in the Inspector.

When spawning a large number of VFX instances (typically missiles), don't forget to use [object pooling](#). If you are new to this concept, take a look at the [introductory video tutorial](#).
